

THE ASYMPTOTIC DIRICHLET PROBLEMS ON MANIFOLDS WITH UNBOUNDED NEGATIVE CURVATURE

RAN JI

ABSTRACT. Elton P. Hsu used probabilistic method to show that the asymptotic Dirichlet problem is uniquely solvable under the curvature conditions $-Ce^{2-\eta}r(x) \leq K_M(x) \leq -1$ with $\eta > 0$. We give an analytical proof of the same statement. In addition, using this new approach we are able to establish two boundary Harnack inequalities under the curvature condition $-Ce^{(2/3-\eta)r(x)} \leq K_M(x) \leq -1$ with $\eta > 0$. This implies that there is a natural homeomorphism between the Martin boundary and the geometric boundary of M . As far as we know, this is the first result of this kind under unbounded curvature conditions. Our proofs are modifications of arguments due to M. T. Anderson and R. Schoen.

1. INTRODUCTION

In this paper we discuss the solvability of the asymptotic Dirichlet problem and the equivalence of the geometric and Martin boundary on manifolds with negative curvature.

Let M be a complete, simply connected n -dimensional Riemannian manifold whose sectional curvature is bounded from above by a negative constant. Fix a base point $p \in M$. It is well known that the exponential map $\exp_p : T_p M \rightarrow M$ is a diffeomorphism. $S(\infty)$, which is defined as the set of equivalence classes of geodesic rays, can be identified with the unit sphere in $T_p(M)$. A basic fact is that $\overline{M} = M \cup S(\infty)$ with the ‘cone topology’ is a compactification of M [SY94].

Given $\varphi \in C^0(S(\infty))$, the asymptotic Dirichlet problem is to find a continuous function f on \overline{M} such that f is harmonic on M and $f = \varphi$ on $S(\infty)$. The case when M has pinched curvature was solved in 1983 independently by Anderson [And83] and Sullivan [Sul83]. Anderson’s approach was to construct appropriate convex sets and use the convexity property of Choi [Cho84]. A simpler proof was given by Anderson and Schoen [AS85] in 1985. In 1992, Borbély was able to replace the lower bound of the curvature by an unbounded growth function. His proof was based upon that of Anderson, namely he proved the following theorem.

Theorem 1.1. ([Bor92]) *Let M be a complete, simply connected Riemannian manifold with negative sectional curvature. Let $r = d(p, \cdot)$ denote the distance function and $\lambda < \frac{1}{3}$ be a positive constant. If the sectional curvature K_M satisfies $K_M(x) \leq -1$ everywhere and $-e^{\lambda r(x)} \leq K_M(x)$ outside a compact subset of M , then the asymptotic Dirichlet problem is uniquely solvable.*

Hsu was able to get a better lower bound of the curvature condition using probabilistic method. His result is as follows.

Theorem 1.2. ([Hsu03]) *Let M be a complete, simply connected Riemannian manifold whose sectional curvature K_M satisfies $-Ce^{\lambda r(x)} \leq K_M(x) \leq -1$ on M for some $\lambda < 2$. Then the asymptotic Dirichlet problem is uniquely solvable.*

We will give an analytical proof of Theorem 1.2 in Section 3 based upon that of Anderson and Schoen [AS85]. A key refinement is that instead of taking the average $\bar{\varphi}$ of the extended function φ in a ball of fixed radius, we let the radius vary. Then with the help of Bishop volume comparison theorem, we can show that even under relaxed curvature growth condition, the argument still works and yields Hsu's result.

On a non-parabolic manifold, i.e., a manifold possesses positive Green's function, one can define the Martin boundary which describes the behavior of harmonic functions at infinity. We will give more details in section 4. A natural question is whether the Martin boundary is the same as the geometric boundary. Anderson and Schoen showed that we can identify them when the manifold has pinched negative curvature.

Theorem 1.3. ([AS85]) *Let M be a complete, simply connected Riemannian manifold whose sectional curvature satisfies $-b^2 \leq K_M \leq -a^2 < 0$. Then there exists a natural homeomorphism $\Phi : \mathcal{M} \rightarrow S(\infty)$ from the the Martin boundary \mathcal{M} of M to the geometric boundary $S(\infty)$. Moreover, Φ^{-1} is Hölder continuous.*

To prove Theorem 1.3, they established two boundary Harnack inequalities, which estimate the growth of positive harmonic functions in cones which vanish continuously at infinity. In Section 5, we relax the curvature assumption in Theorem 1.3 and establish the Harnack inequalities. It follows that the Martin boundary can be identified with the geometric boundary. To be precise, we prove the following theorem.

Theorem 1.4. *Let M be a complete, simply connected Riemannian manifold whose sectional curvature K_M satisfies $-Ce^{\lambda r(x)} \leq K_M(x) \leq -1$ on M for some $\lambda < \frac{2}{3}$. Then there is a natural homeomorphism between the geometric boundary and Martin boundary of M .*

Our result on the Martin boundary is the first one that allows the sectional curvature go to $-\infty$ as $r \rightarrow \infty$.

Remark 1.1 Theorem 1.2 holds for $\lambda < 2$. However, we were able to prove Theorem 1.4 only under the stronger condition $\lambda < \frac{2}{3}$. This is because Theorem 1.4 follows from the boundary Harnack inequalities in Section 5, which we can prove only under the stronger curvature condition. It is possible that the boundary Harnack inequalities and therefore Theorem 1.4 are true under a relaxed curvature condition.

Acknowledgements The author would like to thank Professor Józef Dodziuk for the invaluable support and guidance. The author would also like to thank Professor Zheng Huang and Professor Marcello Lucia for their useful comments and suggestions.

2. PRELIMINARIES

Throughout this section we assume M is a complete, simply connected Riemannian manifold of n dimensions with sectional curvature $K_M(x) \leq -1$.

Denote by $H(-1)$ the two-dimensional hyperbolic plane with constant curvature -1 . We have the following well known Toponogov comparison theorem [SY94].

Theorem 2.1. *Let $\triangle pxy$ be a geodesic triangle in M with vertices p, x, y . Suppose $\triangle \tilde{p}\tilde{x}\tilde{y}$ is the corresponding geodesic triangle in $H(-1)$, such that the corresponding sides have the same length. Then we have*

$$\angle(px, py) \leq \angle(\tilde{p}\tilde{x}, \tilde{p}\tilde{y}),$$

where $\angle(px, py)$ denotes the angle at p between the geodesic segments px and py .

In this proof we assume that all geodesics are parameterized by arc length.

Two geodesic rays γ_1 and γ_2 are said to be equivalent, denoted by $\gamma_1 \sim \gamma_2$ if there exists a constant C such that for any $t \geq 0$ we have

$$d(\gamma_1(t), \gamma_2(t)) \leq C.$$

Define $S(\infty)$, the sphere at infinity, to be

$$S(\infty) = \text{the set of all geodesic rays} / \sim.$$

Let S_p denote the unit sphere in $T_p(M)$. Given $\omega \in S_p$, there exists a unique geodesic ray $\gamma : [0, \infty) \rightarrow M$ satisfying $\gamma(0) = p$ and $\gamma'(0) = \omega$. Two geodesic rays γ_1 and γ_2 starting from p are equivalent if and only if $\gamma_1 = \gamma_2$. At the same time each equivalence class contains a representative emanating from p . Thus $S(\infty)$ can be identified with S_p for each $p \in M$.

Now we can define the cone $C_p(\omega, \delta)$ around ω of angle δ by

$$C_p(\omega, \delta) = \{x \in M : \angle(\omega, \gamma'_{px}(0)) < \delta\},$$

where γ_{px} denotes the geodesic ray starting from p that passes through x . We call

$$T_p(\omega, \delta, R) = C_p(\omega, \delta) \setminus B_p(R)$$

a truncated cone of radius R . We denote $M \cup S(\infty)$ by \overline{M} . Then the set of $T_p(\omega, \delta, R)$ for all $\omega \in S_p$, δ and $R > 0$ and $B_q(r)$ for all $q \in M$ and $r > 0$ form a basis of a topology on \overline{M} , which is called the cone topology. This topology makes \overline{M} a compactification of M [SY94].

Remark 2.1 The cone topology on \overline{M} is independent of the choice of p .

Remark 2.2 Anderson and Schoen showed that if $-b^2 \leq K_M \leq -a^2 < 0$, then the topological structure is C^α , where $\alpha = a/b$.

From now on we identify $S(\infty)$ with S_p and its image under the exponential map $\exp_p(S_p)$. Let (r, θ) be the normal polar coordinates at p . Then $\varphi \in C^0(S(\infty))$ can be written as $\varphi = \varphi(\theta)$. Assume that Theorem 1.2 is true for all $\varphi \in C^\infty(S_p)$. Given $\varphi \in C^0(S_p)$, let $\varphi_n \in C^\infty(S_p)$ be a sequence of functions such that $\varphi_n \rightarrow \varphi$ uniformly. Then there exists a sequence of harmonic functions $u_n \in C^\infty(M) \cap C^0(\overline{M})$ satisfying $u_n(r, \theta) \rightarrow \varphi_n(\theta)$ as $r \rightarrow \infty$. By the maximum principle $u_n \rightarrow u$ uniformly on \overline{M} and $u|_{S(\infty)} = \varphi$. This shows that without loss of generality, we may assume $\varphi \in C^\infty(S_p)$.

Extend φ to $M \setminus \{p\}$ by defining

$$\varphi(r, \theta) = \varphi(\theta)$$

for $r > 0$. We still use the letter φ to denote the extended function. Then φ is smooth and bounded on $M \setminus \{p\}$.

Let

$$\text{osc}_{B_x(d)} \varphi = \sup_{y \in B_x(d)} |\varphi(y) - \varphi(x)|$$

be the oscillation of φ in the geodesic ball $B_x(d)$.

Since $\varphi \in C^\infty(S_p)$, it is Lipschitz continuous on S_p . We have for $y \in B_x(d)$,

$$(1) \quad |\varphi(y) - \varphi(x)| = |\varphi(\theta') - \varphi(\theta)| \leq C|\theta' - \theta| = C\angle(px, py),$$

where θ, θ' are the spherical coordinates of x and y respectively.

Now it is necessary to estimate the angle $\angle(px, py)$.

Lemma 2.2. *Let M be a complete, simply connected Riemannian manifold with sectional curvature $K_M \leq -1$, and let p, x, y be three points in M . Suppose that $d(p, x) = s$, and $y \in B_x(d)$ with $d < s$. We have*

$$\angle(px, py) < \frac{2d}{e^{s-d} - 1}.$$

The proof is based on a computation in the hyperbolic plane and the Topogonov comparison theorem. This Lemma is similar to that in [Bor92]. For completeness, we include the proof here.

Let $\triangle \tilde{p}\tilde{x}\tilde{y}$ be the corresponding geodesic triangle in $H(-1)$ such that $d(\tilde{p}, \tilde{x}) = d(p, x) = s$, $d(\tilde{x}, \tilde{y}) = d(x, y) = d' < d < s$ and $d(\tilde{p}, \tilde{y}) = d(p, y)$. We use the Poincare disk model to compute $\angle(\tilde{p}\tilde{x}, \tilde{p}\tilde{y})$ in the unit Euclidean ball B^2 with metric

$$(2) \quad ds_H^2 = 4 \frac{dr^2 + r^2 d\phi^2}{(1 - r^2)^2},$$

where (r, ϕ) are the polar coordinates of B^2 .

Without loss of generality, we may assume that \tilde{p} is the center of B^n . Let $\tilde{\tilde{x}}$ be the intersection of the geodesic sphere $S_{\tilde{x}}(d)$ and the line segment $\tilde{p}\tilde{x}$. Then $d_H(\tilde{p}, \tilde{\tilde{x}}) = s - d$. From (2) we can easily compute the Euclidean distance between \tilde{p} and $\tilde{\tilde{x}}$:

$$d_E(\tilde{p}, \tilde{\tilde{x}}) = \frac{e^{s-d} - 1}{e^{s-d} + 1}.$$

Let $\tilde{\tilde{y}}$ be the intersection of the geodesic sphere $S_{\tilde{p}}(s - d)$ and the line segment $\tilde{p}\tilde{y}$. Denote by $\text{arc}(\tilde{\tilde{x}}, \tilde{\tilde{y}})$ the circular arc joining $\tilde{\tilde{x}}$ and $\tilde{\tilde{y}}$, l_E and l_H the lengths of curves in Euclidean and hyperbolic metrics respectively. We have $l_H(\text{arc}(\tilde{\tilde{x}}, \tilde{\tilde{y}})) < d_H(\tilde{x}, \tilde{y}) = d'$. In fact, let $\gamma_1(\phi) = (d_E(\tilde{p}, \tilde{\tilde{x}}), \phi)$ and $\gamma_2(\phi) = (r(\phi), \phi)$ be the parameterization of $\text{arc}(\tilde{\tilde{x}}, \tilde{\tilde{y}})$ and the geodesic segment $\tilde{x}\tilde{y}$ respectively. We have

$$|\gamma_1'(\phi)| = \frac{2d_E(\tilde{p}, \tilde{\tilde{x}})}{1 - (d_E(\tilde{p}, \tilde{\tilde{x}}))^2}.$$

Also

$$|\gamma_2'(\phi)| = 2 \frac{\sqrt{r'^2(\phi) + r^2(\phi)}}{1 - r^2(\phi)} \geq \frac{2r(\phi)}{1 - r^2(\phi)}.$$

We have $r(\phi) > d_E(\tilde{p}, \tilde{x})$ for all ϕ since the geodesic ball $B_{\tilde{x}}(d')$ lies completely outside $B_{\tilde{p}}(s-d)$, which implies $|\gamma'_2(\phi)| > |\gamma'_1(\phi)|$ and thus $l_H(\text{arc}(\tilde{x}, \tilde{y})) < d(\tilde{x}, \tilde{y}) = d' < d$. By (2) again we have

$$\begin{aligned} l_E(\text{arc}(\tilde{x}, \tilde{y})) &\leq \frac{1}{2} \cdot (1 - (d_E(\tilde{p}, \tilde{x}))^2) \cdot l_H(\text{arc}(\tilde{x}, \tilde{y})) \\ &< \frac{d}{2} \cdot (1 - (d_E(\tilde{p}, \tilde{x}))^2). \end{aligned}$$

Then

$$\begin{aligned} \angle(\tilde{p}\tilde{x}, \tilde{p}\tilde{y}) = \angle(\tilde{p}\tilde{x}, \tilde{p}\tilde{y}) &= \frac{l_E(\text{arc}(\tilde{x}, \tilde{y}))}{d_E(\tilde{p}, \tilde{x})} \\ &< \frac{d}{2} \cdot \frac{1 - (d_E(\tilde{p}, \tilde{x}))^2}{d_E(\tilde{p}, \tilde{x})} \\ &< \frac{2d}{e^{s-d} - 1}. \end{aligned}$$

By Theorem 2.1 we have $\angle(px, py) \leq \angle(\tilde{p}\tilde{x}, \tilde{p}\tilde{y}) < \frac{2d}{e^{s-d} - 1}$. Lemma 2.2 is proved.

3. PROOF OF THEOREM 1.2

Throughout this section we assume M is a complete, simply connected n -dimensional Riemannian manifold with sectional curvature bounded from above by -1 and satisfies

$$-Ce^{(2-2\delta)r(x)} \leq K_M(x)$$

outside a compact subset of M for some $\delta > 0$.

Remark 1 Without loss of generality, we may assume $-Ce^{(2-2\delta)r(x)} \leq K_M(x) \leq -1$ for some large enough constant C on the whole manifold.

Remark 2 The factor 2 before δ is just for notational convenience.

We follow Anderson and Schoen's argument.

Let

$$d(x) = e^{-(1-\delta)r(x)}.$$

We estimate the oscillation of φ in the geodesic ball $B_x(d(x))$. Combining equation (1) and Lemma 2.2 we see easily that

$$(3) \quad \text{osc}_{B_x(d(x))} \varphi = O(e^{-(2-\delta)r(x)}).$$

Now we take the average $\bar{\varphi}$ of φ in the ball $B_x(d(x))$ in the following way. Let $\chi \in C_0^\infty(\mathbb{R})$ be a function satisfying $0 \leq \chi \leq 1$, $\chi(t) = 0$ for $|t| \geq 1$ and $\chi(t) = 1$ for $|t| \leq 1/4$. Let

$$u(x, y) = \chi(e^{(2(1-\delta)r(x))}) \rho_x^2(y),$$

where $\rho_x = d(x, \cdot)$. We have

$$(4) \quad u(x, y) = \begin{cases} 1 & \text{if } y \in \overline{B_x(d(x)/2)} \\ 0 & \text{if } y \in M \setminus B_x(d(x)). \end{cases}$$

Now define

$$\bar{\varphi}(x) = \frac{\int_M u(x, y) \varphi(y) dy}{\int_M u(x, y) dy}.$$

Since φ is continuous and bounded on $M \setminus \{p\}$, $\bar{\varphi}$ is smooth on M . Then we have

$$\begin{aligned} |\bar{\varphi}(x) - \varphi(x)| &= \frac{\int_{B_x(d(x))} u(x, y) (\varphi(y) - \varphi(x)) dy}{\int_{B_x(d(x))} u(x, y) dy} \\ &\leq \sup_{y \in B_x(d(x))} |\varphi(y) - \varphi(x)| \\ &= \text{osc}_{B_x(d(x))} \varphi \\ &= O(e^{-(2-\delta)r(x)}), \end{aligned}$$

which implies $\bar{\varphi}$ and φ have the same value on $S(\infty)$.

Let

$$v(x) = \int_M u(x, y) dy,$$

it follows from (2) that $\text{Vol}(B_x(d(x)/2)) \leq v(x) \leq \text{Vol}(B_x(d(x)))$.

In the following we will simply write d for $d(x)$, u for $u(x, y)$, ρ for $\rho_x(y)$ and v for $v(x)$ and the operations ∇ and Δ will always be with respect to x . We have

$$\begin{aligned} (5) \quad \Delta \bar{\varphi}(x_0) &= \Delta (\bar{\varphi}(x) - \varphi(x_0))|_{x=x_0} \\ &= \int_M \Delta \left(\frac{u}{v} \right) (\varphi(y) - \varphi(x_0)) dy|_{x=x_0}. \end{aligned}$$

Direct computation gives

$$(6) \quad \Delta \left(\frac{u}{v} \right) = \frac{v \Delta u - 2 \nabla u \cdot \nabla v - u \Delta v}{v^2} + \frac{2u}{v^3} |\nabla v|^2.$$

Since r and ρ are both distance functions, we have $|\nabla r| = |\nabla \rho| = 1$. Together with the fact that $\text{supp } u \subset \overline{B_x(d(x))}$, we have

$$\begin{aligned} (7) \quad \nabla u &= \chi'(e^{(2(1-\delta)r(x)} \rho_x^2(y)) \cdot (e^{2(1-\delta)r} ((2-2\delta) \rho^2 \nabla r + 2\rho \nabla \rho)) \\ &= O(e^{(1-\delta)r}), \end{aligned}$$

here we used $\rho = O(e^{-(1-\delta)r})$.

$$\begin{aligned} (8) \quad \Delta u &= \chi''(e^{(2(1-\delta)r(x)} \rho_x^2(y)) \cdot (e^{2(1-\delta)r} ((2-2\delta) \rho^2 \nabla r + 2\rho \nabla \rho))^2 + \chi'(e^{(2(1-\delta)r(x)} \\ &\cdot (e^{2(1-\delta)r} ((2-2\delta)^2 \rho^2 |\nabla r|^2 + 4(2-2\delta) \rho \nabla r \cdot \nabla \rho + (2-2\delta) \rho^2 \Delta r + 2|\nabla \rho|^2 + 2\rho \Delta \rho)). \end{aligned}$$

We need the following Hessian comparison theorem from [SY94] to estimate Δr and $\Delta \rho$.

Theorem 3.1. *Let M_1 and M_2 be two n -dimensional complete Riemannian manifolds. Assume that $\gamma_i : [0, a] \rightarrow M_i$ ($i = 1, 2$) are two geodesics parametrized by arc length, and γ_i does not intersect the cut locus of $\gamma_i(0)$ for $i = 1, 2$. Let r_i be the distance function*

from $\gamma_i(0)$ on M_i and let K_i be the sectional curvature of M_i . Assume that at $\gamma_1(t)$ and $\gamma_2(t)$, $0 \leq t \leq a$, we have

$$K_1(X_1, \frac{\partial}{\partial \gamma_1}) \geq K_2(X_2, \frac{\partial}{\partial \gamma_2}),$$

where X_i is any unit vector in $T_{\gamma_i(t)}M_i$ perpendicular to $\frac{\partial}{\partial \gamma_i}$. Denote by $H(r_i)$ the Hessian of r_i , then

$$H(r_1)(X_1, X_1) \leq H(r_2)(X_2, X_2),$$

where $X_i \in T_{\gamma_i(a)}M_i$ with $\langle X_i, \frac{\partial}{\partial \gamma_i} \rangle(\gamma_i(a)) = 0$ and $|X_i| = 1$.

Since Δr is the trace of $H(r)$, we have the following corollary.

Corollary 3.2. *Let M be an n -dimensional complete Riemannian manifold. If the sectional curvature satisfies $-k^2 \leq K_M(x) \leq -1$ in the geodesic ball $\overline{B_p(R)}$, then*

$$(n-1) \coth r \leq \Delta r \leq (n-1)k \coth kr$$

for $r \leq R$. In addition,

$$n-1 \leq \Delta r \leq (n-1)(k + \frac{1}{r})$$

for $r \leq R$.

Since $-Ce^{(2-2\delta)r(x)} \leq K_M(x) \leq -1$ in $B_p(r(x))$. By Corollary 3.2 we have $n-1 \leq \Delta r(x) \leq (n-1)(1 + C^{1/2}e^{(1-\delta)r(x)})$ for $r(x) \geq 1$. So

$$(9) \quad \Delta r = O(e^{(1-\delta)r}).$$

Since $-Ce^{(2-2\delta)(r(x)+1)} \leq K_M(x) \leq -1$ for $x \in B_x(d(x)) \subset B_p(r(x)+1)$. By Corollary 3.2 again we have

$$(10) \quad \rho \Delta \rho \leq (n-1)(1 + Ce^{(1-\delta)(r+1)})\rho = O(1)$$

when $d(x)/2 \leq \rho \leq d(x)$. Apply (9) and (10) in (8) and use the fact that $\text{supp } \Delta u \subset \overline{B_x(d(x))} \setminus B_x(d(x)/2)$ and $|\nabla r| = |\nabla \rho| = 1$ we see that

$$(11) \quad \Delta u = O(e^{2(1-\delta)r}).$$

To estimate ∇v we have

$$\begin{aligned} |\nabla v| &= |\nabla \int_M u dy| \\ &\leq \int_M |\nabla u| dy \\ &= \int_{B_x(d(x))} |\nabla u| dy, \end{aligned}$$

thus

$$(12) \quad |\nabla v| = \text{Vol}(B_x(d(x))) \cdot O(e^{(1-\delta)r}).$$

We also have

$$\begin{aligned}
|\Delta v| &= |\Delta \int_M u dy| \\
&\leq \int_M |\Delta u| dy \\
&= \int_{B_x(d(x))} |\Delta u| dy,
\end{aligned}$$

thus

$$(13) \quad |\Delta v| = \text{Vol}(B_x(d(x))) \cdot O(e^{2(1-\delta)r}).$$

Combining (7), (11), (12) and (13), we have the following Lemma.

Lemma 3.3.

$$(14) \quad \Delta\left(\frac{u}{v}\right) = \left(\frac{1}{\text{Vol}(B_x(d/2))} + \frac{\text{Vol}(B_x(d))}{(\text{Vol}(B_x(d/2)))^2} + \frac{(\text{Vol}(B_x(d)))^2}{(\text{Vol}(B_x(d/2)))^3} \right) \cdot O(e^{2(1-\delta)r}).$$

To estimate $\Delta\bar{\varphi}(x)$, we need the following corollary of Bishop volume comparison theorem [Pet06].

Corollary 3.4. *Let M be a complete Riemannian manifold, and $c > 0$ a constant. If $K_M(x) \geq -c^2k^2$ on $B_p(1)$ for some $k \geq 1$. Then $\frac{\text{Vol}(B_p(\frac{1}{k}))}{\text{Vol}(B_p(\frac{1}{2k}))} \leq C_n$, where C_n is a constant that depends only on the dimension of M and c .*

Proof. By Bishop Volume Comparison Theorem, $\frac{\text{Vol}(B_p(R))}{V(-c^2k^2, R)}$ is non-increasing in R for $R \leq 1$, where $V(-c^2k^2, R)$ is the volume of the geodesic balls of radius R in the space form of constant curvature $-c^2k^2$. Thus

$$\frac{\text{Vol}(B_p(\frac{1}{k}))}{V(-c^2k^2, \frac{1}{k})} \leq \frac{\text{Vol}(B_p(\frac{1}{2k}))}{V(-c^2k^2, \frac{1}{2k})},$$

which can be written as

$$\frac{\text{Vol}(B_p(\frac{1}{k}))}{\text{Vol}(B_p(\frac{1}{2k}))} \leq \frac{V(-c^2k^2, \frac{1}{k})}{V(-c^2k^2, \frac{1}{2k})}.$$

In the hyperbolic space of constant curvature $-K^2$, the volume of a ball of radius r is given by

$$(15) \quad V(-K^2, r) = \Omega_n \left(\frac{1}{K}\right)^{n-1} \int_0^r \sinh^{n-1}(Kr) dr,$$

where Ω_n is the surface area of the unit sphere in \mathbb{R}^n .

Computing using (15)

$$V(-c^2k^2, \frac{1}{k}) = \Omega_n \left(\frac{1}{ck}\right)^{n-1} \int_0^{\frac{1}{k}} \sinh^{n-1}(ckr) dr = \Omega_n \left(\frac{1}{ck}\right)^n \int_0^c \sinh^{n-1} r dr,$$

and

$$V(-c^2k^2, \frac{1}{2k}) = \Omega_n(\frac{1}{ck})^{n-1} \int_0^{\frac{1}{2k}} \sinh^{n-1}(ckr)dr = \Omega_n(\frac{1}{ck})^n \int_0^{c/2} \sinh^{n-1}rdr.$$

Now we can take $C_n = \frac{V(-c^2k^2, \frac{1}{k})}{V(-c^2k^2, \frac{1}{2k})} = \frac{\int_0^c \sinh^{n-1}rdr}{\int_0^{c/2} \sinh^{n-1}rdr}$, which is a constant that depends only on n and c . \square

We are now ready to estimate $\Delta\bar{\varphi}(x)$.

$$\begin{aligned} |\Delta\bar{\varphi}(x)| &= \left| \int_M \Delta\left(\frac{u}{v}\right)(\varphi(y) - \varphi(x))dy \right| \\ &\leq \int_{B_x(d(x))} \left| \Delta\left(\frac{u}{v}\right) \right| dy \cdot \text{osc}_{B_x(d(x))} \varphi \\ &\leq \sup_{B_x(d(x))} \left\{ \left| \Delta\left(\frac{u}{v}\right) \right| \right\} \cdot \text{Vol}(B_x(d(x))) \cdot \text{osc}_{B_x(d(x))} \varphi \\ &= \left(\frac{\text{Vol}(B_x(d))}{\text{Vol}(B_x(d/2))} + \frac{(\text{Vol}(B_x(d)))^2}{(\text{Vol}(B_x(d/2)))^2} + \frac{(\text{Vol}(B_x(d)))^3}{(\text{Vol}(B_x(d/2)))^3} \right) \cdot O(e^{-\delta r}). \end{aligned}$$

Observe that $B_x(d(x)) \subset B_p(r(x) + 1)$ and on $B_p(r(x))$, $K_M(x) \geq -Ce^{(2-2\delta)r(x)} = -C(\frac{1}{d(x)})^2$. By Corollary 3.4, we have

$$(16) \quad \frac{\text{Vol}(B_x(d(x)))}{\text{Vol}(B_x(d(x)/2))} = O(1).$$

It follows that

$$(17) \quad \Delta\bar{\varphi} = O(e^{-\delta r}).$$

Define $g(x) = e^{-\delta_0 r(x)}$, where δ_0 is a positive constant to be chosen later. We have

$$\Delta g = g \cdot (-\delta_0 \Delta r + \delta_0^2 |\nabla r|^2).$$

Since $K_M \leq -1$ we have $\Delta r \geq n - 1$, choose $\delta_0 < \delta$ small enough such that

$$(18) \quad -\delta_0 \Delta r + \delta_0^2 |\nabla r|^2 < -(n - 1)\delta_0 + \delta_0^2$$

is less than a negative constant.

Now, since $\Delta\bar{\varphi} = O(e^{-\delta r}) = o(e^{-\delta_0 r}) = o(g)$, there exists a constant $\alpha > 0$ such that

$$\Delta(\alpha g) \leq -|\Delta\bar{\varphi}|,$$

which implies that $\bar{\varphi} - \alpha g$ is subharmonic and $\bar{\varphi} + \alpha g$ is superharmonic. It follows from the classical Perron's method that there exists a harmonic function f such that

$$\bar{\varphi} - \alpha g \leq f \leq \bar{\varphi} + \alpha g.$$

Since $\bar{\varphi}$ and φ have the same boundary value and $g = 0$ on $S(\infty)$, $f = \varphi$ on the boundary. This completes the proof of Theorem 1.2.

4. MARTIN BOUNDARY

Throughout this section we still assume M is a complete, simply connected n -dimensional Riemannian manifold whose sectional curvature satisfies

$$-Ce^{(2-2\delta)r(x)} \leq K_M(x) \leq -1.$$

From Theorem 1.2 we know there exists a nontrivial bounded harmonic function f on M . This implies (cf. [SY94]) that M possesses a positive symmetric Green's function $G(p, x)$. Moreover, if we denote by $G_i(p, x)$ the Green's function on Ω_i with Dirichlet boundary condition, where $\{\Omega_i, i = 1, 2, \dots\}$ is a compact exhaustion of M , then G_i converges uniformly to G on compact subsets of $M \setminus \{p\}$.

We have shown on page 9 that if $\alpha > 0$ is sufficiently small, then

$$\Delta(e^{-\alpha r}) \leq 0$$

on M . Let

$$C_1 = \sup_{\partial B_p(1)} G(p, x)e^{\alpha r(x)} > 0,$$

we have

$$\begin{aligned} G_i(p, x) &\leq G(p, x) \leq C_1 e^{-\alpha r(x)} \text{ on } \partial B_p(1), \\ 0 &= G_i(p, x) < C_1 e^{-\alpha r(x)} \text{ on } \partial \Omega_i, \end{aligned}$$

and

$$0 = \Delta G_i \geq \Delta(C_1 e^{-\alpha r}) \text{ on } \Omega_i \setminus B_p(1).$$

It follows from the maximum principle that

$$G_i \leq C_1 e^{-\delta r} \text{ on } \Omega_i \setminus B_p(1).$$

Passing to the limit

$$G(p, y) \leq C_1 e^{-\delta r(x)} \text{ on } M \setminus B_p(1),$$

which implies that G extends continuously to \overline{M} with value 0 on $S(\infty)$.

For $x, y \in M$, let

$$h_y(x) = \frac{G(x, y)}{G(p, y)}$$

be the normalized Green's function with $h_y(p) = 1$. A sequence $Y = \{y_i\}$ is called fundamental if h_{y_i} converges to a positive harmonic function h_Y on M . Two fundamental sequences Y and \overline{Y} are said to be equivalent if the corresponding limiting positive harmonic functions h_Y and $h_{\overline{Y}}$ are the same.

Definition 4.1. The Martin boundary \mathcal{M} of M is the set of equivalence classes of non-convergent fundamental sequences.

Let $\widetilde{M} = M \cup \mathcal{M}$. For each $y \in M$, all sequences converging to y form an equivalence class $[Y]$. On the other hand, two fundamental sequences that have different limit points in M are not equivalent. Thus \widetilde{M} can be identified with the set of equivalence classes of fundamental sequences. Define a metric ρ on \widetilde{M}

$$(19) \quad \rho([Y], [Y']) = \sup_{B_p(1)} |h_Y(x) - h_{Y'}(x)|$$

for $[Y], [Y'] \in \widetilde{M}$. The topology induced by ρ makes \widetilde{M} a compactification of M .

It is known from [SY94] that if for all θ_1, θ_2 with $0 < \theta_2 < \theta_1 < \pi/4$, there exists a positive constant α depending only on n, C, δ, θ_1 and θ_2 , such that for any positive harmonic function $u \in C^0(\overline{C_p(\theta_1)})$ which vanishes on $\overline{C_p(\theta_1)} \cap S(\infty)$, the Harnack inequality

$$(20) \quad u(x) \leq C_1 u(p') e^{-\alpha r(x)}$$

holds on $T(\theta_2, 1)$, then there is a natural surjection $\Phi : \mathcal{M} \rightarrow S(\infty)$. In fact, let $\{y_k\}$ be a sequence of points converging to $\xi \in S(\infty)$. Since $h_{y_k}(p) = 1$, by the classical Harnack inequality, h_{y_k} converge along some subsequence to a positive harmonic function P_ξ satisfying $P_\xi(p) = 1$. Then the above Harnack inequality implies that P_ξ is continuous on $\overline{M} \setminus \{\xi\}$ and vanishes on $S(\infty) \setminus \{\xi\}$. It follows that $P_\xi \neq P_{\tilde{\xi}}$ if $\xi \neq \tilde{\xi}$. Thus a fundamental sequence has a unique limit point. The map is then well defined and surjective.

Moreover, if for any positive harmonic functions $u, v \in C^0(\overline{C_p(\theta_1)})$ which vanish on $\overline{C_p(\theta_1)} \cap S(\infty)$, we have, for all $x \in T(\theta_2, 1)$,

$$(21) \quad \tilde{C}^{-1} \frac{u(p')}{v(p')} \leq \frac{u(x)}{v(x)} \leq \tilde{C} \frac{u(p')}{v(p')},$$

then Φ defined above is one-to-one and therefore a homeomorphism. For further details, see Chapter II in [SY94].

5. BOUNDARY HARNACK INEQUALITIES

In this section we prove (20) and (21) to establish homeomorphism between \mathcal{M} and $S(\infty)$. We assume M is a complete, simply connected n -dimensional Riemannian manifold whose sectional curvature satisfies

$$-Ce^{(2/3-2\delta)r} \leq K_M \leq -1,$$

unless otherwise stated.

Given $\omega \in S_p$. Let $p' = \exp_p \omega$. Recall that $C_p(\theta) = C_p(\omega, \theta)$ is the cone about ω of angle θ at p , and $T_p(\theta, R) = T_p(\omega, \theta, R) = C_p(\omega, \theta) \setminus B_p(R)$ is the truncated cone.

Let $0 < \theta_2 < \theta_1 < \pi/4$ and $\theta_3 = (\theta_1 + \theta_2)/2$.

We want to prove the following two boundary Harnack inequalities.

Theorem 5.1. *Let u be a positive harmonic function on $C_p(\theta_1)$ which is continuous on $\overline{C_p(\theta_1)}$ and vanishes on $\overline{C_p(\theta_1)} \cap S(\infty)$. Then for all $x \in T(\theta_2, 1)$,*

$$u(x) \leq \tilde{C} e^{-\alpha r(x)} u(p'),$$

where \tilde{C} and α depend only on n, C, δ, θ_1 and θ_2 .

Theorem 5.2. *Let u, v be two positive harmonic functions on $C_p(\theta_1)$ which are continuous on $\overline{C_p(\theta_1)}$ and which vanish on $\overline{C_p(\theta_1)} \cap S(\infty)$. Then for all $x \in T(\theta_2, 1)$,*

$$\tilde{C}^{-1} \frac{u(p')}{v(p')} \leq \frac{u(x)}{v(x)} \leq \tilde{C} \frac{u(p')}{v(p')},$$

where \tilde{C} depends only on n, C, δ, θ_1 and θ_2 .

First we need to construct a cut-off function with small second derivatives.

Lemma 5.3. *Given two constants α and β , there exists $\varphi \in C^\infty(M)$ and a constant $R_0 > 0$ such that*

$$\begin{cases} \varphi = \alpha & \text{on } T(\theta_2, R_0), \\ \varphi = \beta & \text{on } \partial C_p(\theta_1) \setminus B_p(R_0), \\ |\nabla \varphi| = O(e^{-r}) & \text{on } T(\theta_2, R_0), \\ |\Delta \varphi| = O(e^{-(2/3+\delta)r}) & \text{on } T(\theta_2, R_0). \end{cases}$$

Proof. Let $\psi \in C^\infty([0, \pi])$ be a function satisfying $0 \leq \psi \leq 1$, $\psi(t) = 0$ for $t \in [0, \theta_2 + \epsilon]$ and $\psi(t) = 1$ for $t \in [\theta_1 - \epsilon, \theta_1 + \epsilon]$, where $\epsilon < (\theta_1 - \theta_2)/2$ is a small positive constant. Set

$$\tilde{\psi}(x) = \psi(\angle(px, v)).$$

$\tilde{\psi}$ is smooth and bounded on $M \setminus \{p\}$. We take the average φ of $\tilde{\psi}$ in the ball $B_x(e^{(-1/3+\delta)r(x)})$ by defining

$$\varphi(x) = \frac{\int_M \chi(e^{(2/3-2\delta)r(x)}) \rho_x^2(y) \tilde{\psi}(y) dy}{\int_M \chi(e^{(2/3-2\delta)r(x)}) \rho_x^2(y) dy},$$

where $\chi \in C_0^\infty(\mathbb{R})$ is a cut-off function satisfying $0 \leq \chi \leq 1$, $\chi(t) = 0$ for $|t| \geq 1$ and $\chi(t) = 1$ for $|t| \leq \frac{1}{4}$. The proof that φ is our desired cut-off function is very similar to that of Theorem 1.2 on page 9. \square

We will need the following gradient estimate for positive harmonic functions due to Yau.

Theorem 5.4. ([Yau75]) *Let N be a complete Riemannian manifold of dimension n . Suppose that the Ricci curvature on $B_p(R)$ is bounded from below by $-(n-1)K$ for some constant $K \geq 0$. If u is a positive harmonic function on $B_p(R)$, then for any $0 < \epsilon < 1$, we have, for all $x \in B_{\epsilon R}$,*

$$\frac{|\nabla u|}{u} \leq \tilde{C} \left(\frac{1}{R} + \sqrt{K} \right),$$

where \tilde{C} is a constant depending only on n and ϵ .

Applying Theorem 5.4 on our manifold M we get the following corollary.

Corollary 5.5. *Let M be a complete, simply connected n -dimensional Riemannian manifold with $-Ce^{(2/3-2\delta)r} \leq K_M \leq -1$. If u is a positive harmonic function on M , then*

$$\left| \frac{\nabla u}{u} \right|(x) \leq \tilde{C} e^{(1/3-\delta/2)r(x)},$$

where \tilde{C} depends only on n , C and δ .

Proof. For every $x \in M$, let

$$R = \frac{2/3 - \delta}{2/3 - 2\delta} \cdot r(x) = C_1 r(x),$$

with $C_1 > 1$. We have

$$K_M \geq -Ce^{(2/3-2\delta)R} = -Ce^{(2/3-\delta)r}$$

on $B_p(R)$.

Apply Theorem 5.4 with $\epsilon = 1/C_1$ to obtain

$$\left| \frac{\nabla u}{u} \right| \leq \tilde{C}e^{(1/3-\delta/2)r}$$

on $B_p(R/C_1) = B_p(r(x))$. □

Lemma 5.6. *Let u be a positive harmonic function on $C_p(\theta_3)$ which is continuous on $\overline{C_p(\theta_3)}$ and which vanishes on $\overline{C_p(\theta_3)} \cap S(\infty)$. Then for all $x \in T(\theta_2, 1)$,*

$$u(x) \leq \tilde{C}e^{-\alpha r(x)} \sup_{\partial C_p(\theta_3)} u,$$

where α is a constant depending only on n, C, δ, θ_1 and θ_2 .

Proof. By lemma 5.3, there exists $\varphi \in C^\infty(M)$ and a constant $R_1 > 0$ such that

$$\begin{cases} \varphi = 0 & \text{on } T(\theta_2, R_1), \\ \varphi = 1 & \text{on } \partial C_p(\theta_3) \setminus B_p(R_1), \\ |\nabla \varphi| = O(e^{-r}) & \text{on } T(\theta_3, R_1), \\ |\Delta \varphi| = O(e^{-(2/3+\delta)r}) & \text{on } T(\theta_3, R_1). \end{cases}$$

Consider $e^{-\alpha r}$, where $\alpha < \frac{2}{3} + \delta$ is sufficiently small. We have

$$\begin{aligned} \Delta e^{-\alpha r} &= e^{-\alpha r}(\alpha^2 - \alpha \Delta r) \\ &\leq e^{-\alpha r}(\alpha^2 - (n-1)\alpha) < 0. \end{aligned}$$

Since $\Delta \varphi = O(e^{-(2/3+\delta)r})$, we have $|\Delta \varphi| < -C_1 \Delta e^{-\alpha r}$ on $T(\theta_3, R_0)$ for C_1 and R_0 sufficiently large.

Let $f = \varphi + \tilde{C}e^{-\alpha r}$. We have $\Delta f \leq 0$ if $\tilde{C} > C_1$. Also $f \geq \varphi = 1$ on $\partial C_p(\theta_3) \setminus B_p(R_0)$ and $f \geq 1$ on $\overline{B_p(R_0)}$, provided \tilde{C} is sufficiently large.

Now consider $\bar{u} = u / \sup_{\partial C_p(\theta_3)} u$. \bar{u} is harmonic and $\bar{u} \leq 1$ on $\partial C_p(\theta_3)$. We have $\Delta(\bar{u} - f) \geq 0$ on $C_p(\theta_3)$ and $\bar{u} - f \leq 0$ on $\partial C_p(\theta_3)$. By the maximum principle, $\bar{u} \leq f$ on $C_p(\theta_3)$. In particular,

$$u(x) \leq f(x) \sup_{\partial C_p(\theta_3)} u = \tilde{C}e^{-\alpha r} \sup_{\partial C_p(\theta_3)} u$$

for all $x \in T(\theta_2, R_0)$. □

We are now ready to prove Theorem 5.1. By Lemma 5.6, it is sufficient to show that harmonic functions satisfying the given conditions and $u(p') = 1$ are uniformly bounded on $\partial C_p(\theta_3)$. In the following we will use $C_1, C_2, \dots, \alpha_1, \alpha_2, \dots$ and R_1, R_2, \dots to denote positive constants depending only on n, C, δ, θ_1 and θ_2 .

By lemma 5.3, there exists $\varphi \in C^\infty(M)$ with $\frac{2}{3} \leq \varphi \leq 1$ and a constant $R_0 > 0$ such that

$$\begin{cases} \varphi = \frac{2}{3} \text{ on } T(\theta_3, R_0), \\ \varphi = 1 \text{ on } \partial C_p(\theta_1) \setminus B_p(R_0), \\ |\nabla \varphi| = O(e^{-r}) \text{ on } T(\theta_1, R_0), \\ |\Delta \varphi| = O(e^{(-2/3-\delta)r}) \text{ on } T(\theta_1, R_0). \end{cases}$$

Consider the function u^φ . Direct computation gives

$$(22) \quad \nabla u^\varphi = u^\varphi (\log u \nabla \varphi + \varphi \nabla \log u),$$

$$(23) \quad \Delta u^\varphi = u^\varphi (|\log u \nabla \varphi + \varphi \nabla \log u|^2 + \log u \Delta \varphi + 2 \nabla \varphi \cdot \nabla \log u + \varphi \Delta \log u).$$

Using Corollary 5.5, we have

$$(24) \quad |\nabla \log u| = O(e^{(1/3-\delta/2)r})$$

and

$$(25) \quad \begin{aligned} |\log u(x)| &= |\log u(x) - \log u(p')| \\ &\leq \int_\gamma |\nabla \log u| \\ &\leq \sup_{B_p(r(x))} |\nabla u| \cdot d(x, p') \\ &\leq \tilde{C} e^{(1/3-\delta/2)r(x)} (r+1) \\ &= o(e^{r/3}), \end{aligned}$$

where γ is the geodesic segment connecting x and p' .

Observe that

$$\Delta \log u = \frac{\Delta u}{u} - \frac{|\nabla u|^2}{u^2} = -|\nabla \log u|^2.$$

Therefore

$$(26) \quad \Delta u^\varphi \leq u^\varphi (C_1 e^{(-1/3-\delta/2)r} + (\varphi - \varphi^2) |\nabla \log u|^2).$$

Let $\psi \in C^\infty(\mathbb{R})$ be a function such that

$$\begin{cases} 1 \leq \psi \leq C_2, \\ \psi'(t) = -\frac{1}{|t| \log^2 |t|} \text{ for } |t| \geq R_1, \\ -\psi'(t) \geq 12|\psi''(t)| \geq 0 \text{ for all } t. \end{cases}$$

Such a function could be constructed by elementary calculus.

Let $\xi = \log u$. Set

$$F(x) = \psi(\xi(x) - e^{-\beta r(x)}) \cdot u^\varphi,$$

where β is a positive number to be determined later. We have for $\psi = \psi(\xi(x) - e^{-\beta r(x)})$,

$$\nabla \psi = \psi' \cdot (\nabla \xi + \beta e^{-\beta r} \nabla r),$$

$$\Delta \psi = \psi'' \cdot |\nabla \xi + \beta e^{-\beta r} \nabla r|^2 + \psi' \cdot (-|\nabla \xi|^2 + \beta e^{-\beta r} (\beta \Delta r - \beta^2)).$$

Therefore

$$\begin{aligned}
\Delta F &= \psi \Delta u^\varphi + \Delta \psi u^\varphi + 2\nabla \psi \cdot \nabla u^\varphi \\
&= \psi \Delta u^\varphi + \psi'' u^\varphi \cdot |\nabla \xi + \beta e^{-\beta r} \nabla r|^2 \\
&\quad + \psi' u^\varphi \cdot ((2\varphi - 1)|\nabla \xi|^2 + 2\xi \nabla \varphi \cdot \nabla \xi + 2\beta e^{-\beta r} \xi \nabla \varphi \cdot \nabla r \\
&\quad + 2\beta \varphi e^{-\beta r} \nabla \xi \cdot \nabla r + e^{-\beta r} (\beta \Delta r - \beta^2)).
\end{aligned}$$

Using (24) (25) and (26), we obtain the following estimate

$$\begin{aligned}
\Delta F &\leq u^\varphi [C_1 C_2 \psi e^{(-1/3-\delta/2)r} + 2\beta^2 e^{-2\beta r} |\psi''| + \psi' \cdot (-C_3 e^{(-1/3-\delta/2)r} \\
&\quad + e^{-\beta r} (\beta \Delta r - \beta^2 - \beta \varphi))] + u^\varphi |\nabla \xi|^2 [2|\psi''| + (2\varphi - 1 - \beta \varphi e^{-\beta r}) \psi'] \\
&\leq u^\varphi (C_4 e^{(-1/3-\delta/2)r} + \psi' \cdot (\beta \Delta r - \beta^2 - \beta) e^{-\beta r}) + u^\varphi \psi' |\nabla \xi|^2 (\frac{1}{6} - \beta e^{-\beta r}).
\end{aligned}$$

Here we have used the inequalities $2/3 \leq \varphi \leq 1$ and $\nabla \xi \cdot \nabla r \leq |\nabla \xi|^2 + 1$.

Since $\Delta r \geq n - 1$, we can take $\beta < \delta/4$ sufficiently small so that

$$(27) \quad (\beta \Delta r - \beta^2 - \beta) e^{-\beta r} \geq C_5 e^{-\beta r}.$$

At points x such that $\xi = \xi(x) \geq R_1 + 1$, from (25) we have

$$(28) \quad \xi = o(e^{r/3}) \text{ and } \log \xi = O(r),$$

Together with the definition of ψ , this yields

$$\begin{aligned}
\psi' \cdot (\beta \Delta r - \beta^2 - 2\beta) e^{-\beta r} &\leq -\frac{1}{|\xi| \log^2 |\xi|} C_5 e^{-\beta r} \\
&\leq -C_6 \frac{1}{r^2} e^{-(1/3+\beta)r} \\
&\leq -C_7 e^{-(1/3+\delta/4)r}
\end{aligned}$$

for r sufficiently large. Here we have used that $e^{-(1/3+\beta)r}/r^2 = O(e^{-(1/3+\delta/4)r})$ since $\beta < \delta/4$.

It follows that for $\xi \geq R_1 + 1$, we have

$$\begin{aligned}
(29) \quad \Delta F &\leq u^\varphi (C_4 e^{(-1/3-\delta/2)r} - C_7 e^{-(1/3+\delta/4)r}) \\
&\quad + u^\varphi \psi' |\nabla \xi|^2 (\frac{1}{6} - 2\beta e^{-\beta r}).
\end{aligned}$$

If R_2 is sufficiently large then $C_4 e^{(-1/3-\delta/2)r} - C_7 e^{-(1/3+\delta/4)r} < 0$ and $\frac{1}{6} - 2\beta e^{-\beta r} > 0$ for $r \geq R_2$, so that $\Delta F \leq 0$ on $T(\theta_1, R_2)$.

The remaining case is when $\xi \leq R_1 + 1$. We then have $u = e^\xi \leq C_8 = e^{R_1+1}$ is bounded. In addition, $u^\varphi \leq C_8 u^{1/2}$ and $u^\varphi |\xi| \leq C_9 u^{1/2}$. Using the fact that $|\psi|$, $|\psi'|$ and $|\psi''|$ are all bounded, we conclude that

$$\Delta F \leq C_{10} u^{1/2} |\nabla \xi|^2 + C_{11} e^{-\beta r}.$$

Define

$$(30) \quad G = F + C_{12} u^{1/2} + e^{-\alpha_1 r}.$$

This is a positive function with $\alpha_1 < \beta$ and C_{11} to be determined. It is clear that $G_F = C_{12}u^{1/2} + e^{-\alpha_1 r}$ is superharmonic. Therefore

$$\begin{aligned}
 (31) \quad \Delta G &= \Delta F + C_{12}u^{1/2}\left(-\frac{1}{4}|\nabla \xi|^2\right) + e^{-\alpha r}(\alpha^2 - \alpha \Delta r) \\
 &\leq C_{10}u^{1/2}|\nabla \xi|^2 + C_{11}e^{-\beta r} - \frac{C_{12}}{4}u^{1/2}|\nabla \xi|^2 - C_{13}e^{-\alpha r} \\
 &= \left(C_{10} - \frac{C_{12}}{4}\right)u^{1/2}|\nabla \xi|^2 + C_{11}e^{-\beta r} - C_{13}e^{-\alpha r} \\
 &\leq 0
 \end{aligned}$$

on $T(\theta_1, R_3)$ if C_{12}, C_{13} and R_3 are sufficiently large.

Combine (29), (31) and the superharmonicity of $G - F$, we have for all ξ ,

$$\Delta G \leq 0$$

on $T(\theta_1, R_0)$ with $R_0 = \max(R_2, R_3)$.

Since u is harmonic,

$$\Delta(C_{14}G - u) \leq 0$$

on $T(\theta_1, R_0)$, where $C_{14} > 1$ is a constant to be determined. Observe that $F = \psi u \geq u$ on $\partial C_p(\theta_1)$. Therefore

$$C_{14}G - u \geq C_{14}F - u \geq 0$$

on $\partial C(\theta_1) \setminus B_p(R_3)$. If C_{14} is sufficiently large, we also have

$$C_{14}G - u \geq 0$$

on $\partial B_p(R_3) \cap C(\theta_1)$. By the maximum principle,

$$C_{14}G \geq u$$

on $T(\theta_1, R_0)$. In particular, on $T(\theta_3, R_0)$ we have

$$\begin{aligned}
 u \leq C_{14}G &= C_{14}\psi u^{2/3} + C_{12}C_{14}u^{1/2} + e^{-\alpha_1 r} \\
 &\leq C_1C_{14}u^{2/3} + C_9C_{10}u^{1/2} + e^{-\alpha_1 r},
 \end{aligned}$$

which implies that u is bounded on $T(\theta_3, R_0)$. By the gradient estimate u is also bounded on $\overline{B_p(R_0)}$. Therefore, positive harmonic functions on $C_p(\theta_1)$ which vanish on $\overline{C_p(\theta_1)} \cap S(\infty)$ are uniformly bounded on $\overline{C_p(\theta_3)} = \overline{T(\theta_3, R_0)} \cup \overline{B_p(R_0)}$. Now applying Lemma 5.6 we have for all $x \in T(\theta_2, R_0)$,

$$u(x) \leq \tilde{C}e^{-\alpha r(x)}u(p').$$

The truncated cones $T(\theta_2, R_0)$ and $T(\theta_2, 1)$ differ by a precompact set, it then follows from the gradient estimate that the Harnack inequality above actually holds on $T(\theta_2, 1)$. This completes the proof of Theorem 5.1.

Proof of Theorem 5.2. Without loss of generality we may assume that $u(p') = v(p') = 1$.

By Theorem 5.1, we have

$$(32) \quad u, v \leq C_1e^{-\alpha_1 r}.$$

Let $\xi = -\log u$. From the gradient estimate we have

$$(33) \quad \nabla \xi = O(e^{(1/3-\delta/2)r})$$

and

$$(34) \quad \xi = o(e^{r/3}).$$

Thus we have

$$(35) \quad C_2 r \leq \xi \leq C_3 e^{r/3}$$

on $T(\theta_1, R_1)$. It follows from (32) and (34) that

$$(36) \quad \xi^{-\epsilon} \geq e^{-\epsilon r/3} \geq C_4 v$$

for $\epsilon > 0$ sufficiently small.

We will construct a function $F \in C^\infty(C_p(\theta_1))$ satisfying

$$\begin{aligned} (i) & \Delta F \leq 0 \quad \text{on } T(\theta_1, R_0), \\ (ii) & F \geq v \quad \text{on } \partial T(\theta_1, R_0), \\ (iii) & F \leq C_5 u \quad \text{on } T(\theta_2, R_0). \end{aligned}$$

It will then follow from the maximum principle that $v \leq F$ on $T(\theta_1, R_0)$. In particular, $v \leq C_5 u$ on $T(\theta_2, R_0)$, which gives the first inequality in Theorem 5.2. By exchanging u and v we get the second inequality immediately.

We now proceed to construct F satisfying (i),(ii) and (iii). By Lemma 5.3, there exists $\varphi \in C^\infty(M)$ with $0 \leq \varphi \leq 1$ such that

$$(37) \quad \begin{cases} \varphi = 0 & \text{on } T(\theta_2, R_1), \\ \varphi = 1 & \text{on } \partial C_p(\theta_1) \setminus B_p(R_1), \\ |\nabla \varphi| = O(e^{-r}) & \text{on } T(\theta_1, R_1), \\ |\Delta \varphi| = O(e^{-(2/3+\delta)r}) & \text{on } T(\theta_1, R_1). \end{cases}$$

Consider the function $f = u^{1-\varphi} \xi^{-\epsilon \varphi}$. We have

$$\begin{aligned} f &= u \quad \text{on } T(\theta_2, R_1), \\ f &= \xi^{-\epsilon} \geq C_4 v \quad \text{on } \partial C_p(\theta_1) \setminus B_p(R_1), \end{aligned}$$

and

$$(38) \quad \nabla f = f \cdot (\xi \nabla \varphi - (1-\varphi) \nabla \xi - \epsilon \log \xi \nabla \varphi - \epsilon \varphi \nabla \log \xi),$$

$$\begin{aligned} \Delta f &= f \cdot (|\xi \nabla \varphi - (1-\varphi) \nabla \xi - \epsilon \log \xi \nabla \varphi - \epsilon \varphi \nabla \log \xi|^2 \\ &\quad + \xi \Delta \varphi + 2 \nabla \varphi \cdot \nabla \xi - (1-\varphi) \Delta \xi - \epsilon \log \xi \Delta \varphi - 2 \epsilon \nabla \log \xi \cdot \nabla \varphi - \epsilon \varphi \Delta \log \xi). \end{aligned}$$

Observe that

$$(39) \quad \Delta \xi = -\frac{\Delta u}{u} + |\nabla \xi|^2 = |\nabla \xi|^2,$$

and

$$(40) \quad \Delta \log \xi = \frac{\Delta \xi}{\xi} - \frac{|\nabla \xi|^2}{\xi^2} = \frac{|\nabla \xi|^2}{\xi} - |\nabla \log \xi|^2.$$

Therefore by (33), (35) and (37) we have

$$(41) \quad \Delta f \leq f \cdot [(\varphi^2 - \varphi) |\nabla \xi|^2 + \epsilon \varphi (1 - 2\varphi) \frac{|\nabla \xi|^2}{\xi} + (\epsilon^2 \varphi^2 + \epsilon \varphi) |\nabla \log \xi|^2 + C_6 e^{-(1/3+\delta/2)r}].$$

Let $\psi \in C^\infty(\mathbb{R})$ be a function such that

$$\begin{cases} 1 \leq \psi \leq C_7, \\ \psi'(t) = \frac{1}{|t| \log^2 |t|} \text{ for } |t| \geq R_2, \\ \psi'(t) \geq 12|\psi''(t)| \geq 0 \text{ for all } t. \end{cases}$$

Set

$$(42) \quad F(x) = \psi(\xi + e^{-\beta r(x)}) \cdot f.$$

We have for $\psi = \psi(\xi + e^{-\beta r(x)})$,

$$\nabla \psi = \psi' \cdot (\nabla \xi - \beta e^{-\beta r} \nabla r),$$

$$\Delta \psi = \psi'' \cdot |\nabla \xi - \beta e^{-\beta r} \nabla r|^2 + \psi' \cdot (\Delta \xi + e^{-\beta r}(\beta^2 - \beta \Delta r)).$$

Then we have

$$\begin{aligned} \Delta F &= \psi \Delta f + \Delta \psi f + 2 \nabla \psi \cdot \nabla f \\ &= \psi \Delta f + \psi'' f \cdot |\nabla \xi - \beta e^{-\beta r} \nabla r|^2 \\ &\quad + \psi' f \cdot (-|\nabla \xi|^2 + e^{-\beta r}(\beta^2 - \beta \Delta r)) + 2 \psi' \cdot (\nabla \xi - \beta e^{-\beta r} \nabla r) \cdot \nabla f \\ &\leq \psi f [(\varphi^2 - \varphi) |\nabla \xi|^2 + \epsilon \varphi (1 - 2\varphi) \frac{|\nabla \xi|^2}{\xi} + (\epsilon^2 \varphi^2 + \epsilon \varphi) |\nabla \log \xi|^2 \\ &\quad + C_6 e^{-(1/3+\delta/2)r}] + \psi' f [(2\varphi - 3) |\nabla \xi|^2 - 2\epsilon \varphi \frac{|\nabla \xi|^2}{\xi} + 2\beta(1 - \varphi) e^{-\beta r} \nabla \xi \cdot \nabla r \\ &\quad + 2\epsilon \beta \varphi e^{-\beta r} \nabla \log \xi \cdot \nabla r + C_8 e^{-\beta r}(\beta^2 - \beta \Delta r)] \\ &\leq \psi f [\varphi(\varphi - 1) |\nabla \xi|^2 + \varphi(\epsilon - 2\epsilon \varphi) \frac{|\nabla \xi|^2}{\xi} + \varphi(\epsilon^2 \varphi + \epsilon) |\nabla \log \xi|^2 \\ &\quad + C_6 e^{-(1/3+\delta/2)r}] + \psi' f [(2\varphi - 3 + 2\beta(1 - \varphi + \epsilon \varphi)) |\nabla \xi|^2 \\ &\quad + C_9 e^{-2\beta r} + C_8 e^{-\beta r}(\beta^2 - \beta \Delta r)]. \end{aligned}$$

Here we have used the inequalities $e^{-\beta r} \nabla \xi \cdot \nabla r \leq |\nabla \xi|^2 + e^{-2\beta r}$ and $|\nabla \xi|^2 / \xi \leq |\nabla \xi|^2$.

As in the proof of Theorem 5.1, we can choose $\beta < \delta/4$ to be sufficiently small and R_0 sufficiently large so that

$$\begin{aligned} \Delta F &\leq C_6 C_7 e^{-(1/3+\delta/2)r} + C_{10} e^{-\beta r} / (\xi \log^2 \xi) \\ &\leq C_6 C_7 e^{-(1/3+\delta/2)r} + C_{11} e^{-(1/3+\delta/4)r} \\ &\leq 0 \end{aligned}$$

on $T(\theta_1, R_0)$. This is possible because $\xi = o(e^{r/3})$ and $\log \xi = o(r)$.

We already know that

$$F = \psi f \geq C_4 v$$

on $\partial C_p(\theta_1) \setminus B_p(R_0)$. Therefore $C_{12} F \geq v$ on $\partial T(\theta_1, R_0)$ if C_{12} is sufficiently large. Since v is harmonic, by the maximum principle, we have $C_{12} F \geq v$ on $\overline{T(\theta_1, R_0)}$. In particular,

$$v \leq C_{12} F \leq C_7 C_{12} u$$

on $\overline{T(\theta_2, R_0)}$.

Since $u(p') = v(p') = 1$, by the gradient estimate we have

$$C_{13} \leq u, v \leq C_{14}$$

on $B_p(R_0) \cap T(\theta_2, 1)$. Then $\frac{u}{v} \geq \tilde{C}^{-1}$ on $T(\theta_2, 1)$ with $\tilde{C} = \max(\frac{C_{13}}{C_{14}}, C_7 C_{12})$. \square

Remark 5.1 As remarked in Section 4, Theorem 1.4 follows immediately from Theorem 5.1 and Theorem 5.2.
